Introduction

Tele-epidemiology has fundamentally transformed infectious disease surveillance by integrating satellite remote sensing, geographic information systems (GIS), artificial intelligence (AI), mobile health platforms, and digital communication networks. These technologies offer unprecedented capacity to monitor ecological changes, predict disease emergence, and coordinate rapid public health responses across vast geographical scales (Elemuwa *et al.,* 2024; Kakwi *et al.,* 2024a; 2024b; 2025; Henry & Moruufu, 2025). However, the rapid expansion of technological capability has significantly outpaced the development of ethical communication strategies, robust governance mechanisms, and equity-focused implementation approaches. Consequently, a critical gap persists: while remote surveillance systems can generate vast quantities of health intelligence, there is insufficient evidence on how to translate this data into trusted, socially responsible, and actionable public health interventions. This systematic review addresses this gap by synthesizing evidence across technological, environmental, ethical, and governance domains to develop a comprehensive framework that aligns digital innovation with public trust, environmental sustainability, and equitable health outcomes. By positioning ethical communication as the central mechanism linking surveillance capacity to public health action, this review provides novel insights for policymakers, technologists, and health practitioners seeking to build resilient, human-centred surveillance systems in an era of climate change and emerging infectious diseases. The primary objective of this systematic review was to synthesize current evidence on technological innovations, environmental applications, ethical communication practices, governance structures, equity considerations, and One Health implications within tele-epidemiological systems. Secondary objectives were to: (1) identify the cross-cutting challenges,

including data privacy, algorithmic transparency, digital inequities, and community participation, that limit the effectiveness of remote surveillance; (2) evaluate the role of governance capacity and participatory communication as determinants of sustainable implementation; and (3) develop a conceptual framework, the Ethical Communication Framework for Tele-Epidemiology (ECF-TE), that integrates technological integrity, environmental intelligence, ethical governance, participatory communication, and policy translation.

Methodology

This study employed a systematic narrative review design, adhering to the PRISMA 2020 framework. A comprehensive search strategy was executed across PubMed, Scopus, Web of Science, and Google Scholar, covering literature published between January 2000 and December 2025. The search combined controlled vocabulary and free-text keywords across four conceptual domains: (i) tele-epidemiology and digital surveillance technologies; (ii) ethics, communication, and governance; (iii) environmental epidemiology and exposure assessment; and (iv) policy and implementation contexts. Eligible studies included quantitative, qualitative, mixed-methods, systematic reviews, policy analyses, and implementation studies addressing remote disease monitoring, environmental surveillance, or digital health governance. Grey literature from WHO, World Bank, and institutional repositories was incorporated to capture operational and policy perspectives. Two independent reviewers screened records and extracted data, with methodological quality assessed using design-specific appraisal tools (CASP, ROBINS-I, and JBI checklists). Due to substantial heterogeneity in study designs, technologies, and outcome measures, a meta-analysis was not feasible; instead, a narrative thematic synthesis approach was adopted, organized into five analytical domains: technological innovations; environmental determinants; ethical communication and public trust; governance and policy frameworks; and equity, One Health, and community engagement. A total of 95 studies met the eligibility criteria and were included in the final synthesis.

Results

The evidence synthesis revealed that tele-epidemiological systems increasingly incorporate satellite remote sensing, GIS-based surveillance, drones, mobile health applications, artificial intelligence, and digital early-warning platforms to enhance disease monitoring and prediction. Environmental surveillance approaches increasingly integrate climatic variables, ecological indicators, land-use characteristics, and pollution-related exposures to strengthen understanding of disease-environment interactions. However, the review identified a critical disconnect between technological capability and effective implementation. Major cross-cutting challenges included: inadequate ethical governance (reported across the majority of governance-focused studies); limited transparency in data practices and algorithmic decision-making; concerns regarding privacy, informed consent, and accountability; uneven digital access and infrastructure limitations, particularly in low- and middle-income countries (LMICs); and insufficient community participation in surveillance design and implementation. The synthesis further identified governance capacity, participatory communication, and contextual adaptation as critical determinants of sustainable implementation. Systems perceived as opaque, externally controlled, or insensitive to local cultural expectations were more likely to encounter resistance, whereas participatory approaches incorporating community engagement and clear risk communication improved acceptance and sustainability. The evidence demonstrated that technological innovation alone is insufficient to guarantee public health impact; rather, successful implementation depends on the integration of ethical safeguards, transparent communication, and equitable governance structures. The review also highlighted the growing importance of One Health approaches, which integrate human, animal, and environmental health data to improve preparedness for climate-sensitive and environmentally mediated diseases.

Conclusion

Tele-epidemiology is evolving beyond a technology-centred surveillance model towards an integrated socio-technical public health system. This review demonstrates that the future effectiveness of remote disease monitoring depends not only on data acquisition and analytical

capacity but on the ability to govern, communicate, and apply information responsibly. The principal contribution of this study is the development of the Ethical Communication Framework for Tele-Epidemiology (ECF-TE), which positions technological integrity, environmental intelligence, ethical governance, participatory communication, and policy translation as interconnected components required for trusted and equitable surveillance. The framework advances tele-epidemiology from a data-centric model towards an ethically embedded model in which surveillance effectiveness is understood as the outcome of interactions among technological capability, environmental understanding, governance structures, and social trust. The findings underscore that systems incorporating transparency, accountability, privacy protection, and community participation are more likely to achieve sustained adoption and public health impact, whereas systems prioritizing data generation without adequate governance risk undermining trust, widening inequalities, and limiting effectiveness. Future tele-epidemiological initiatives should adopt ethical-by-design principles, with robust governance and data protection frameworks addressing privacy, cybersecurity, data ownership, algorithmic accountability, and responsible data sharing. Interoperability with existing public health surveillance systems should be prioritised to reduce fragmentation and improve decision-making. Workforce capacity should be strengthened in digital epidemiology, GIS, remote sensing, AI governance, and risk communication. Digital inequalities should be addressed through infrastructure investment, digital literacy, and inclusive design, while communities should participate as active partners throughout the surveillance lifecycle. Long-term investment should support sustainable One Health surveillance ecosystems for emerging infectious and climate-related health threats, guided by harmonised international standards. Particular attention should be given to implementation capacity and digital equity in low- and middle-income countries.
